

Proposal for Predicting Diabetes Based on Medical Reports

Problem Statement:

Diabetes is a widespread chronic disease that poses significant health risks if not managed effectively. Identifying individuals at risk of developing diabetes early is crucial for preventive care and reducing the burden on healthcare systems. However, predicting diabetes can be challenging due to the complex interplay of genetic, environmental, and lifestyle factors reflected in medical reports.

Objective:

To develop a predictive model that analyzes medical report data to determine the likelihood of an individual having or developing diabetes. The project will utilize historical medical data and machine learning techniques to identify key factors contributing to diabetes.

Expected Outcomes:

1. A machine learning model capable of accurately predicting diabetes risk based on medical report data.
2. Insights into key factors influencing diabetes risk, such as glucose levels, BMI, and lifestyle indicators.
3. A report or dashboard visualizing predictions and trends in diabetes risk among individuals.
4. Recommendations for preventive measures or interventions based on the findings.
